Abstract

The buffer capacity concept is extended on dynamic redox systems, realized according to titrimetric mode, where changes in pH are accompanied by changes in potential E values; it is the basic novelty of this paper. Two examples of monotonic course of the related curves of potential E vs. and pH vs. Φ relationships were considered. The systems were modeled according to GATES/GEB principles.

Keywords: Thermodynamics of electrolytic redox systems; Buffer capacity; GATES/GEB.

Introduction

The buffer capacity concept is usually referred to as a measure of resistance of a solution (D) on pH change, affected by an acid or base, added as a titrant T, i.e., according to titrimetric mode; in this case, D is termed as titrand.

The titration is a dynamic procedure, where V mL of titrant T, containing a reagent B (C mol/L), is added into V0 mL of titrand D, containing a substance A (C0 mol/L). The advance of a titration $B(C,V) \Rightarrow A(C0,V0)$, denoted for brevity as $B \Rightarrow A$ is characterized by the fraction titrated [1-4]

$$\Phi = \frac{C \cdot V}{C_0 \cdot V_0}$$ (1)

That introduces a kind of normalization (independence on V0 value) for titration curves, expressed by pH=pH(Φ), and E=E(Φ) for potential E [V] expressed in SHE scale. The redox systems with one, two or more electron-active elements are modeled according to principles of Generalized Approach to Electrolytic Systems with Generalized Electron Balance involved (GATES/GEB), described in details in [5-16], and in references to other authors' papers cited therein.

According to earlier conviction expressed by Gran [17], all titration curves: pH=pH(Φ) and E=E(Φ), were perceived as monotonic; that generalizing statement is not true [7], however. According to contemporary knowledge, full diversity in this regard is stated, namely: (1o) monotonic pH=pH(Φ) and monotonic E=E(Φ) [18-20]; (2o) monotonic pH=pH(Φ) and non-monotonic E=E(Φ) [6]; (3o) non-monotonic pH=pH(Φ) and monotonic E=E(Φ) [5]; (4o) non-monotonic pH=pH(Φ), and non-monotonic E=E(Φ) [7].

Examples of Titration Curves pH=pH(Φ) and E=E(Φ) in redox systems

In this paper, we refer to the disproportionating systems: (S1) NaOH $\Rightarrow$ HIO and (S2) HCl $\Rightarrow$ NaIO, characterized by monotonic changes of pH and E values during the related titrations (i.e., the case 1o). In both instances, the values: V0=100, C0=0.01, and C=0.1 were assumed. The set of equilibrium data [18-20] applied in calculations, presented in **Table 1**, is completed by the solubility of solid iodine, I2(s), in water, equal 1.33·10-3 mol/L. The related algorithms, prepared in MATLAB for S1 (NaOH $\Rightarrow$ HIO) S2 (HCl $\Rightarrow$ NaIO) system according to the GATES/GEB principles, are presented in Appendices 1 and 2.

The titration curves: pH=pH(Φ) and E=E(Φ) presented in **Figures 1 and 2** are the basis to formulation of dynamic buffer capacities in the systems S1 and S2.

Dynamic acid-base buffer capacities β_v and B_v

Dynamic buffer capacity was referred previously only to acid-

Figure 1 (A) pH=pH(Φ) and (B) E=E(Φ) relationships plotted for the system NaOH $\Rightarrow$ HIO.

base equilibria in non-redox systems [3,21-23]. However, the dynamic (β_V) and windowed (B_V) buffer capacities can be also related to acid-base equilibria in redox systems. The β_V is formulated as follows [3,21].

$$\beta_V = \left| \frac{dc}{dpH} \right| \qquad (2)$$

where

$$c = \frac{CV}{V_0 + V} \qquad (3)$$

It is the current concentration of B in D+T mixture, at any point of the titration. In the simplest case, D is a solution of one substance A (C_0 mol/L), and then Equation 3 can be rewritten as follows

$$c = \Phi \cdot \frac{C_0 C}{C + \Phi \cdot C_0} \qquad (4)$$

Figure 2   (A) pH=pH(Φ) and (B) E=E(Φ) relationships plotted for the system HCl $\Rightarrow$ NaIO.

where Φ is the fraction titrated (Equation 1). Then we get

$$\beta_V = \frac{dc}{d\Phi} \cdot \left| \frac{d\Phi}{dpH} \right| = \frac{C_0 \cdot C^2}{(C + \Phi \cdot C_0)^2} \cdot \frac{1}{|\eta|} = \frac{c^2}{C_0 \cdot |\eta|} \tag{5}$$

where

$$\eta = \frac{dpH}{d\Phi} \tag{6}$$

is the sharpness index on the titration curve. For comparative purposes, the absolute values,$|\beta_V|$ and $|\eta|$, for β_V (Equations 1 and 5) and η (Equation 6) are considered. At $C_0/C \ll 1$ and small Φ value, from Equation 3 we get $\hat{a}_V = \ddot{O}^2 \cdot C_0 / |\varsigma|$.

The β_V value is the point–assessment and then cannot be used in the case of finite pH–changes (ΔpH) corresponding to an addition of a finite volume of titrant (β_V is a non–linear function of pH). For this purpose, the 'windowed' buffer capacity, B_V, defined by the formula [3,21].

$$B_V = \left| \frac{\Delta c}{\Delta pH} \right| \tag{7}$$

where

$$\frac{\Delta c}{\Delta pH} = \frac{1}{\Delta pH} \cdot \int_{pH}^{pH+\Delta pH} \beta_V \cdot dpH = \frac{c(pH + \Delta pH) - c(pH)}{\Delta pH} \tag{8}$$

has been suggested. From extension in Taylor series we have

$$\frac{\Delta c}{\Delta pH} = \beta_V + \frac{d\beta_V}{dpH} \cdot \frac{\Delta pH}{2} + \frac{d^2\beta_V}{dpH^2} \cdot \frac{(\Delta pH)^2}{6} + \dots = \beta_V + \sum_{k=1}^{\infty} \left(\frac{d^k\beta_V}{dpH^k} \right)_{pH} \cdot \frac{(\Delta pH)^k}{(k+1)!} \tag{9}$$

where

$$\left(\frac{d^k c}{dpH^k} \right)_{pH} = \left(\frac{d^{k-1}\beta_V}{dpH^{k-1}} \right)_{pH} \tag{10}$$

From Equations 7 and 9 we see that βV is the first approxima-

tion of BV. One should take here into account that finite changes (ΔpH) in pH, e.g. ΔpH=1, are involved with addition of a finite volume of a reagent endowed with acid–base properties, here: base NaOH, of a finite concentration, C.

Dynamic redox buffer capacities β_V^E and B_V^E

In similar manner, one can formulate dynamic buffer capacities B_V^E and B_V^E, involved with infinitesimal and finite changes of potential E values:

$$\beta_V^E = \left| \frac{dc}{dE} \right| \tag{11}$$

$$B_V^E = \left| \frac{\Delta c}{\Delta E} \right| \tag{12}$$

Where c is defined by Equation 2, and then we have

$$\frac{\Delta c}{\Delta E} = \frac{1}{\Delta E} \cdot \int_{E}^{E+\Delta E} \beta_V^E \cdot dE = \frac{c(E + \Delta E) - c(E)}{\Delta E}$$

$$\frac{\Delta c}{\Delta E} = \beta_V^E + \sum_{k=1}^{\infty} \left(\frac{d^k\beta_V^E}{dE^k} \right)_E \cdot \frac{(\Delta E)^k}{(k+1)!} \tag{13}$$

where

$$\frac{d^k c}{dE^k} = \left(\frac{d^{k-1}\beta_V^E}{dE^{k-1}} \right)_E \tag{14}$$

Graphical presentation of dynamic buffer capacities in redox systems

Referring to dynamic redox systems represented by titration curves presented in **Figures 1 and 2**, we plot the relationships: β_V vs. Φ, β_V vs. pH, β_V vs. E, and β_V^E vs. Φ, β_V^E vs. pH, β_V^E vs. E for the systems: (S1) NaOH $\Rightarrow$ HIO; (S2) HCl $\Rightarrow$ NaIO. The relations: (A) β_V vs. Φ, (B) β_V vs. pH, (C) β_V vs. E and (D) β_V^E vs. Φ, (E) β_V^E vs. pH, (F) β_V^E vs. E are plotted in **Figures 3 and 4**.
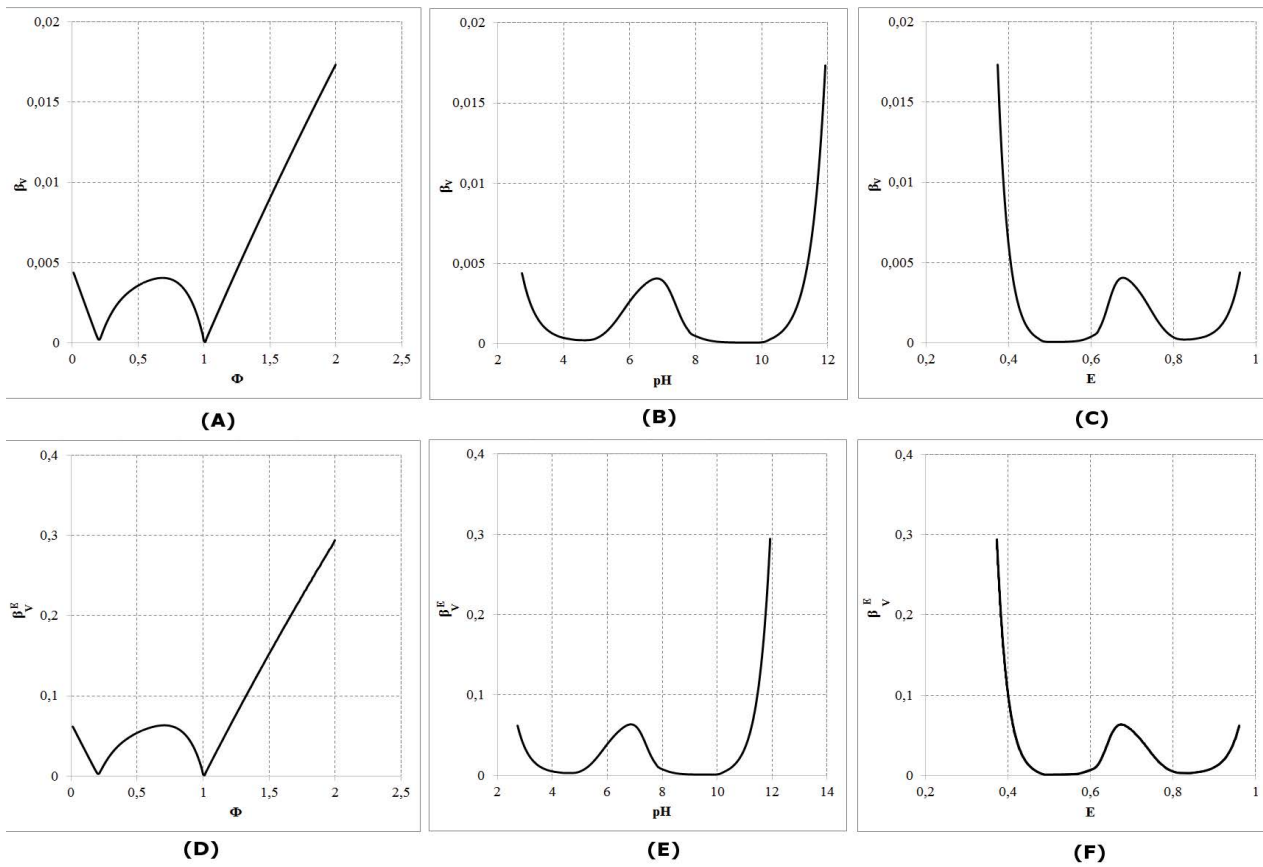

Figure 3 The relations: (**A**) β_V vs. Φ, (**B**) β_V vs. pH, (**C**) β_V vs. E and (**D**) β_V^E vs. Φ, (**E**) β_V^E vs. pH, (**F**) β_V^E vs. E for (S1) NaOH $\Rightarrow$ HIO.
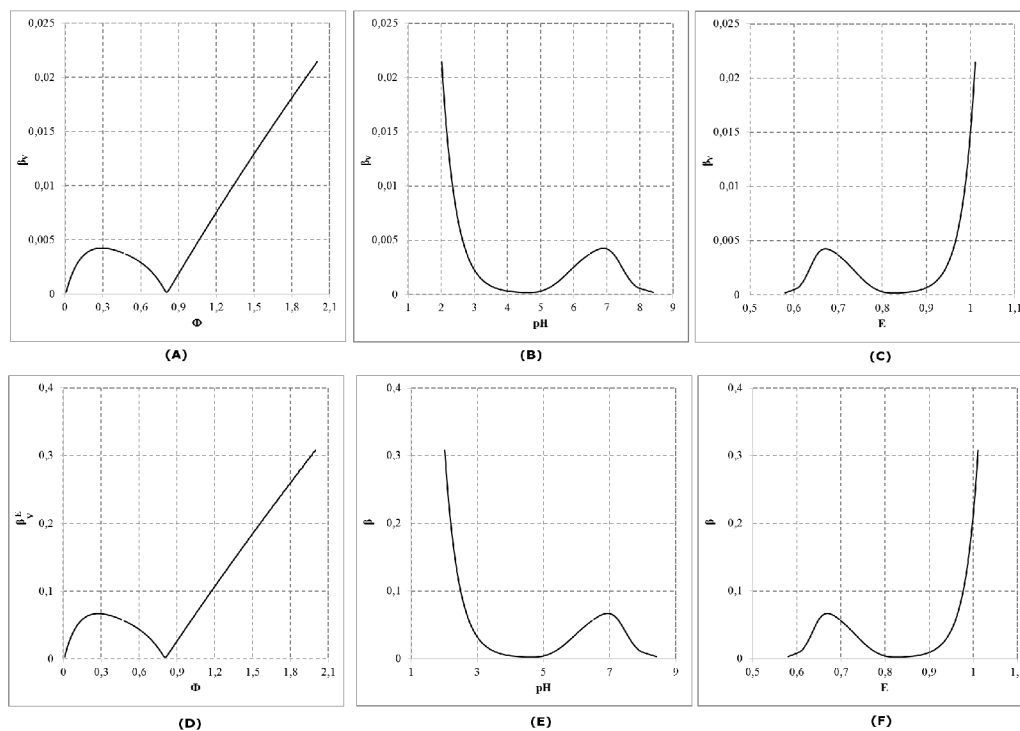

Figure 4 The relations: (**A**) β_V vs. Φ, (**B**) β_V vs. pH, (**C**) β_V vs. E and (**D**) β_V^E vs. Φ, (**E**) β_V^E vs. pH, (**F**) β_V^E vs. E for (S2) HCl $\Rightarrow$ NaIO.

Discussion

Disproportionation of the solutes considered (HIO or NaIO) in D occurs directly after introducing them into pure water. The disproportionation is intensified, by greater pH changes, after addition of the respective titrants: NaOH (in S1) or HCl (in S2), and the monotonic changes of $E=E(\Phi)$ and $pH=pH(\Phi)$ occur in all instances.

All attainable equilibrium data related to these systems are included in the algorithms implemented in the MATLAB computer program (see Appendices 1 and 2). In all instances, the system of equations was composed of: generalized electron balance (GEB), charge balance (ChB) and concentration balances for particular elements $\neq$ H, O.

In the system S1, the precipitate of solid iodine, $I_{2(s)}$, is formed, see **Figure 5**. In the (relatively simple) redox system S2, we have all four basic kinds of reactions; except redox and acid-base reactions, the solid iodine ($I_{2(s)}$) is precipitated and soluble complexes: I_2Cl^{-1}, ICl and ICl_2^{-1} are formed, see **Figure 6A**. Note that $I_{2(s)} + I^{-1} = I_3^{-1}$ is also the complexation reaction.

In the system S2, all oxidized forms of Cl^{-1} were involved, i.e. the oxidation of Cl^{-1} ions was thus pre-assumed. This way, full "democracy" was assumed, with no simplifications [18-20]. However, from the calculations we see that HCl acts primarily as a disproportionating, and not as reducing agent. The oxidation of Cl^{-1} occurred here only in an insignificant degree **(Figure 6B)**; the main product of the oxidation was Cl_2, whose concentration was on the level ca. 10^{-16}-10^{-17} mol/L.

Conclusion

The redox buffer capacity concepts: $\hat{a}_V$ and $\underset{c_0 = c + c^2 \cdot \Phi}{\ldots}$ can be principally related to monotonic functions. This concept looks awkwardly for non-monotonic functions $pH=pH(\Phi)$ and/or $E=E(\Phi)$ specified above (2°–4°) and exemplified in **Figures 7-9** presented in Appendix 3. For comparison, in isohydric (acid-base) systems, the buffer capacity strives for infinity. In particular, it occurs in the titration HB (C,V) $\Rightarrow$ HL (C_0,V_0), where HB is a strong monoprotic acid HB and HL is a weak monoprotic acid characterized by the dissociation constant $K_1=[H^{+1}][L^{-1}]/[HL]$; at $4K_W/C^2 \ll 1$, the isohydricity condition is expressed here by the Michałowski formula $C_0 = C + C^2 \cdot \Phi \cdot \frac{K_1}{\ldots}$ [24-26].

The formula for the buffer capacity, suggested by Bard et al. [27] after Levie [28], is not correct. Moreover, it involves formal potential value, perceived as a kind of conditional equilibrium constant idea, put in (apparent) analogy with the simplest static acid-base buffer capacity, see criticizing remarks in the study by Michałowska-Kaczmarczyk et al. [29]; it is not adaptable for real redox systems.

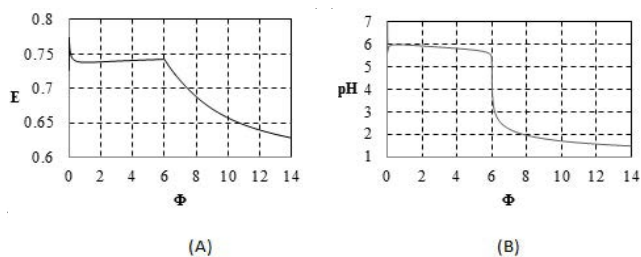

Figure 9 Case (4°): the (**A**) non-monotonic pH=pH(Φ) and (**B**) non-monotonic E=E(Φ) functions for the system HI $\Rightarrow$ KIO$_3$ presented in the study by Michałowski [7].

Buffered solutions are commonly applied in different procedures involved with classical (titrimetric, gravimetric) and instrumental analyses [30-33]. There are in close relevance to isohydric solutions [24-26] and pH-static titration [4,34], and titration in binary-solvent systems [12,35]. Buffering property is usually referred to an action of an external agent (mainly: strong acid, HB, or strong base, MOH) inducing pH change, ΔpH, of the solution. Redox buffer capacity is also involved with the problem of interfacing in CE-MS analysis, and bubbles formation in reaction 2 H$_2$O=O$_{2(g)}$ + 4H^{+1} + 4e^{-1} at the outlet electrode in CE [36-39].

In the paper, a nice proposal of "*slyke*", as the name for (acid-base, pH) buffer capacity unit, has been raised [40].
