## Preliminary Process of Developing Multiple Programs for Promoting Family Health with a Vulnerable Child

Received: January 06, 2016; Accepted: February 11, 2017; Published: February 20, 2017

## Introduction

Vulnerable children in this study included the disabled children with Duchenne Muscular Dystrophy (DMD)/Spinal Muscular Atrophy (SMA), attention deficit hyperactivity disorder (ADHD), or chromosome abnormality (Turner syndrome or Klinefelter syndrome, TS/KS). DMD/SMA is a primary genetic chronic disorder of motor and lung function and scoliosis by early muscle weakness that can lead to difficulties with walking, respiratory complications, and impact independence in daily activities [1]. ADHD is significant problems with attention and inhibitory control that cause attention deficits, hyperactivity, or impulsiveness with academic difficulties as are problems in relationship with family members [2]. TS/KS, a chromosome structure is altered and govern physical and medical characteristics, such as susceptibility to lymphedema, osteoporosis and fractures, structural malformations of the kidney, autoimmune thyroiditis, diabetes mellitus, inflammatory bowel disease [3-5], or higher risks for scoliosis, lordosis, and kyphosis [6].

The vulnerable situations have been found to exhibit relatively enduring health behavior, health values, family support, and health risk perceptions of families that can be developed and performed [7,8]; and situations of disability/worse health problem can compromise the independence and functional capacity of the vulnerable children thus making them dependent on caregivers, and inducing functional impairment in family, social, and academic settings that was similar in these groups of children and caused problems regarding families' health issues and general dysfunctional family support [9-13]. These untreated health problems may lead to major complications or complex limitations in activity and participation family time [3,14-17]. Policy programs for the vulnerable population were created and changed as generation change how that influenced families perception of their health and family support. However, empirical evidence to guide health professional collaborate with families to provide family health promotion intervention. Especially, disturbances in family function were related to a high risk of family depression [7,9,13].

A few years ago, first author would like to test the model of family health promotion development, the "concepts and its relationship of family health promotion model" consists of four dynamically Jih-Yuan Chen<sup>1</sup>, Ming-Hong Yen<sup>2</sup>, Ying-Huey Lin<sup>3</sup>, Shu-Hui Hu<sup>4</sup>, Hong-Sen Chen<sup>5</sup>, Meng-Chi Liu<sup>3</sup>, Mei-Chyn Chao<sup>6</sup> and Wen-Ling Chen<sup>3</sup>

interacting components those may affect by environment factors: 1) Family health capacity: including family hardiness (similar to family resilience) and family support, 2) Family health behavior as meaning family health promotion lifestyle, 3) Family health status: including family general function (family assessment device-general function, FAD-GF), and general health (Duke Health Profile, Duke), 4) Health needs: including health crisis assessment, health risk, and nutrition needs. Each component is brief stated later in the content that is summarized in **Figure 1**.

A family health capacity variable was derived from testing the family stress, resources, and adaptation model [18]. Families of children with DMD/SMA could share the burdens of their stressful situations, endure the illness change, and find personal significance or meaning, then, family adaptation and the long-term care of their children could be improved. Researchers evaluate family hardiness and use it to provide support with family support for the families that can evidence to promote family functioning [19] and family health [18]. Family could not get resources to assist families to coping; the family might have already depleted family energy and resources when the chronic condition deteriorated one's health. The ability to maintain a balance between change and stability has been referred as one nature of healthy family functioning **(Figure 2)** [20].

## **Family Health Behavior**

Family health behavior is important role in maintaining health promotion life pattern to foster self-protective action to prevent disease, reducing behaviors that increase health risk, facilitating effective adaptation to and coping with illness, and focusing on the potential and strength for growth within families of children with disability. Health promotion life pattern which dimensions of health behaviors included nutrition, exercise, health responsibility, stress management, social support, and life appreciation [21], that was also presented by family health promotion lifestyles.

Family health status combines the outcome of family general function and general health **(Tables 1 and 2)**.

Family functioning is a reliable predictor of parent adjustment that can be found to solve problems, to present affection, and to meet families' needs to promote and achieve the balance of family health status [10,18]. Health needs assessment included personal health risk factors which a wide variety of behavioral lifestyle interventions have demonstrated effective risk reduction

in terms of weight loss or prevention of weight gain, improved diet, increased exercise and activity, smoking cessation, and reduction in hazardous alcohol consumption [22]. Subjects will be interviewed including health needs assessment, family health behaviors, family health capacity, and health status, which measurements include personal health risk factors assessment examine body structure (height/wrist ratio, body mass index, lumbar/waist ration), nutritional assessment including BMI condition, health problem crisis increase, body weight assessment compare with ideal body weight, nutrition condition (body weight/ideal body weight ratio), and health risk (lumbar/ waist ration).

Research indicates that family transition of children with muscular dystrophy impacts the actions of FHPL and threatens family health, even inducing severe family distress, including depression, feelings of helplessness or isolation, infertility, and inadequacy [23,24]. Increasing the family members' cognition by helping them play a healthy role, understand potential health risks, share in the sick child's rehabilitation, sharing information about medical care; and assessing factors related to the family health promotion model would help the families of children with muscular dystrophy support family coherence by retaining quality of life via support groups and seeking social welfare, even with limited time and resources. In addition, these factors could help provide sick children wholesome learning and caring environment, facilitate healthy lifestyles, and extend to lifelong learning program **(Tables 3 and 4)** [25].

Authors conducted the model derived from family stress, resources, and adaptation model to see which major factors are influencing on action of family health promotion and understand its relationship of family health promotion model [11]. Previous five studies had published to determine relationship between families' perception of health and support in the care of vulnerable children [12] to determine predictors of family function in DMD and SMA family [26], to determine the demographic predictors of lower health promotion lifestyles scores in caregivers of children with disabilities [27], to test the model of family resource and health perspective of children with Turner syndrome [28]. The other two studies were not to be published to determine the level of QOL in family caregivers of disabled children and investigated the associations among dimensions of health promotion lifestyles (HPLS) and dimensions of mental health in QOL and to test the family health promotion model for family of a child with DMD and SMA.

To promote accurate reporting of family health promotion related variables, subjects will be given quality control measures to minimize errors in assessment of family health promotion. Measures to be taken by demographics, family structure analysis, family power structures, family health life pattern, family hardiness index, family APGAR, family health assessment device-general function, duke health profile. As well as to check reliability and validity of all the previous state measurements by item response checking (item total correlations) and factor analysis (exploratory factor analysis and confirmatory factor analysis), and to test structure of family health promotion

model. At last authors detected the conditions of health needs, family capacity, family health behaviors, family health status in families of children with vulnerable diseases, that to compare the differences of family health needs, health capacities, health behaviors and health status between parents; to compare the differences of family health needs, health capacities, health behaviors and health status among the three difference disease groups; and to analysis the predictors influence on family health needs, health capacities, health behaviors and health status. The results will be discussed on the other paper including the multiple programs for the families' health promotion of children with a vulnerable disease.
