Cervical cancer is a type of cancer that occurs in the cells of the cervix — the lower part of the uterus that connects to the vagina. Various strains of the human papillomavirus (HPV), a sexually transmitted infection, play a role in causing most cervical cancer. A malignant tumour of the cervix, the lowermost part of the uterus. A malignant tumour of the lower-most part of the uterus (womb) that can be prevented by PAP smear screening and a HPV vaccine. Symptoms include bleeding in between periods and after sexual intercourse. Foul smelling white discharge and low back pain or lower abdominal pain may also occur. In some cases there may be no symptoms. Treatments include surgery, radiation and chemotherapy. Cervical cancer happens when cells change in women's cervix, which connects their uterus with vagina. This cancer can affect the deeper tissues of their cervix and may spread to other parts of their body (metastasize), often the lungs, liver, bladder, vagina, and rectum. Cervical cancer is a type of cancer that starts in the cervix. The cervix is a hollow cylinder that connects the lower part of a woman's uterus to her vagina. Most cervical cancers begin in cells on the surface of the cervix. All women are at risk for cervical cancer. It occurs most often in women over age 30. Long-lasting infection with certain types of human papillomavirus (HPV) is the main cause of cervical cancer. HPV is a common virus that is passed from one person to another during sex. At least half of sexually active people will have HPV at some point in their lives, but few women will get cervical cancer.

Cancer is a disease in which cells in the body grow out of control. Cancer is always named for the part of the body where

it starts, even if it spreads to other body parts later. When cancer starts in the cervix, it is called cervical cancer. The cervix connects the vagina (birth canal) to the upper part of the uterus. The uterus (or womb) is where a baby grows when a woman is pregnant.

Many women with cervical cancer don't realize they have the disease early on, because it usually doesn't cause symptoms until the late stages. When symptoms do appear, they're easily mistaken for common conditions like menstrual periods and urinary tract infections (UTIs).

The main types of cervical cancers are squamous cell carcinoma and adenocarcinoma.

Most (up to 9 out of 10) cervical cancers are squamous cell carcinomas.

Most of the other cervical cancers are adenocarcinomas.

Less commonly, cervical cancers have features of both squamous cell carcinomas and adenocarcinomas.

Squamous cell carcinomas begin in the thin, flat cells that line the bottom of the cervix. This type of cervical cancer accounts for about 80 percent of cervical cancers.

Adenocarcinomas of the cervix develop in the glandular cells that line the upper portion of the cervix. Cervical adenocarcinomas make up about 20 percent of cervical cancers.

Sometimes, both types of cells are involved in cervical cancer. Other types of cancer can develop in the cervix, but these are rare. For example, metastatic cervical cancer starts in the cervix and spreads to other parts of the body.
